

DNS Rebuild — Who Changes What

wergonic.com — collapse 3 environments to 2, one clean checklist per system.

2026-08-03 · Zone: Cloudflare · Apps: DigitalOcean App Platform · Four owners: **Cloudflare** · **DigitalOcean** · **Mobile** · **Web**. (Backend code = no change; its settings are DO env vars.)

Target names. Two envs — **staging** (daily, auto-deploy) & **production** (gated release). Flat single-level naming; the `.cloud.` infix is gone.

COMPONENT	PRODUCTION	STAGING
Landing	wergonic.com	—
Client app	cloud.wergonic.com	cloud-staging.wergonic.com
API	api.wergonic.com	api-staging.wergonic.com
Admin	admin.wergonic.com	admin-staging.wergonic.com

At a glance — who touches what

CHANGE	CLOUDFLARE	DIGITALOCEAN	MOBILE	WEB
Email / DKIM fix	✓	—	—	—
Rename staging → cloud-staging	✓	✓	✓	✓
Fix prod API → api.wergonic.com	✓	✓	✓	✓
Add admin domain	✓	✓	—	✓
Landing on wergonic.com	✓	✓	—	—
Delete legacy / dev env	✓	✓	—	—

Every row where two owners have ✓ must be paired: add the DNS record *and* attach the domain to the app, or it won't serve.

CLOUDFLARE**DNS zone: wergonic.com****Add (proxied / orange)**

- **ADD** CNAME cloud-staging → client-panel-staging-2-hwwkh.ondigitalocean.app
- **ADD** CNAME admin → ♦ prod admin app · CNAME admin-staging → ♦ staging admin app
- **ADD** CNAME @ (wergonic.com) → ♦ landing app (after it's deployed in DO — Phase 4)
- **REPOINT** CNAME api → wergonic-django-docker-backend-c3so9.ondigitalocean.app (was the dead ...98t32)

Fix proxy / rules

- **UN-PROXY** set firebase1._domainkey & firebase2._domainkey to **DNS-only** (grey) — proxying breaks DKIM.
- **RULE** Redirect www → https://wergonic.com; **remove** the old rule that sends wergonic.com/www → wergonic.se.

Delete

- **DELETE** api.cloud · api-staging.cloud · staging.cloud · dev.cloud · api-dev.cloud
- **DELETE** mail · pop · smtp · ftp (legacy Inleed) · the email.* A/MX/TXT (keep the email NS delegation)

DIGITALOCEAN**App Platform****Attach custom domains to apps**

- Staging client app → cloud-staging.wergonic.com · Staging backend → api-staging.wergonic.com
- Prod backend app (...c3so9) → api.wergonic.com
- Admin app(s) → admin.wergonic.com (+ admin-staging) · Landing app → wergonic.com + www

Update backend env vars (DO dashboard)

- STAGING_FRONTEND_BASE_URL = https://cloud-staging.wergonic.com
- PROD_BACKEND_BASE_URL = https://api.wergonic.com (from api.cloud)
- Delete all DEV_* vars.

Decommission (cost saving)

- Old prod backend ...98t32 · django-dev · client-panel-dev-2
- ♦ Copy the ingress hostnames of the **landing**, **admin** and **admin-staging** apps here (App → Settings → Domains) — Cloudflare needs them.

MOBILE**wergonic-flutter**

- lib/env.dart: rename env dev→staging; staging baseUrl=https://cloud-staging.wergonic.com, apiBaseUrl=https://api-staging.wergonic.com; prod baseUrl=https://cloud.wergonic.com, apiBaseUrl=https://api.wergonic.com.
- android/app/src/main/AndroidManifest.xml: deep-link host staging.cloud.wergonic.com → cloud-staging.wergonic.com (keep cloud.wergonic.com).
- Rebuild & release; verify cloud-staging.wergonic.com/.well-known/assetlinks.json returns 200.

WEB wergonic-web-apps (client + admin)

- VITE_API_BASE_URL per build: production → `https://api.wergonic.com`, staging → `https://api-staging.wergonic.com` (set in the DO app build env / CI).
- **Fix typo** VITE_API_BASE_URL → VITE_API_BASE_URL (both `.env.example` + wherever it's read).
- CI `.github/workflows/wergonic-ci-cd.yaml`: rename mode development → staging; branch map dev→staging, main→production.
- Admin: point its API base at `api / api-staging`.

Backend (wergonic-django-backend): no code change — CORS/CSRF are env-driven and follow the DO vars above.

Order of operations

Left = who acts. Always add + test, then delete.

PHASE	OWNER(S)	DO
0 · now	Cloudflare	Un-proxy DKIM; delete mail/pop/smtp/ftp + email.* dupes. Safe, no app impact.
1 · staging	CF → DO → Mobile+Web	Add cloud-staging + attach domains → ship staging code → test → CF delete staging.cloud/api-staging.cloud.
2 · prod API	CF → DO → Mobile+Web	Repoint api + attach to prod app → ship prod-API code → test → CF delete api.cloud.
3 · admin	DO + CF + Web	Attach admin domains → add CF records → set admin API base.
4 · landing	DO + CF	Deploy landing + attach wergonic.com/www → point apex → remove the .se redirect.
5 · cleanup	CF + DO	Delete dev.cloud/api-dev.cloud; decommission old DO apps.

The one rule: for any hostname, add the Cloudflare record and attach the domain in DigitalOcean, test it live, and only then delete the old one. Prod never goes down.

Verify (after each phase)

```
curl -sI https://cloud-staging.wergonic.com/ | head -1           # 200
curl -sI https://cloud-staging.wergonic.com/.well-known/assetlinks.json # 200 (mobile links)
curl -sI https://api.wergonic.com/api/v1/docs/ | head -1       # 200 (was 530)
curl -sI https://wergonic.com/ | head -1                       # 200 landing (not
301→.se)
dig +short wergonic.com TXT | grep spf1                         # exactly ONE line
```
